Noise, Filtering and Smoothing

Prof. Dr. Elli Angelopoulou

Pattern Recognition Lab (Computer Science 5) University of Erlangen-Nuremberg

Noise Sources

- Photon noise: variation in the #photons falling on a pixel per time interval T.
- Saturation: each pixel can only generate a limited amount of charge.
- Blooming: saturated pixel can overflow to neighboring pixels.

Noise Sources - continued

- Thermal noise: heat can free electrons and generate a response when there is none.
- Electronic noise.
- Burned pixels.
- Black is not black.
- Keep in mind: Camera response may not be linear over the number of photons falling on a surface (camera gamma)

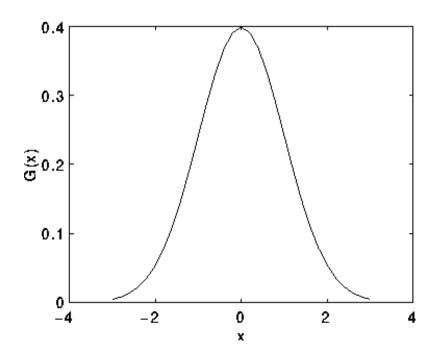

Detector Noise

Page 4

- Source of noise: the discrete nature of radiation, i.e. the fact that each imaging system is recording an image by counting photons.
- Can be modeled as an independent additive noise which can be described by a zero-mean Gaussian.

Salt and Pepper Noise

Page 5

- A common form of noise is caused by data drop-out noise.
- It is also known as commonly referred to as intensity spikes, speckle, or salt and pepper noise.

Sources of error:

- Errors in the data transmission.
- Burned pixels: the corrupted pixels are either set to the maximum value (which looks like snow in the image) or are set to zero ("peppered" appearance), or a combination of the two.
- Single bits are flipped over.
- Isolated/localized noise. It only affects individual pixels.

Filtering

Page 6

- Most of the images we capture are noisy.
- Goal:

Noisy Image_{in} → Filter → Clean Image_{out}

This notion of filtering is more general and can be used in a wide range of transformations that we may want to apply to images.

Mathematically, a filter H can be treated as a function on an input image I:

$$H(I) = R$$

• Note: We use the terms *filter* and *transformation* interchangeably.

Elli Angelopoulou

Noise, Filtering and Smoothing

Linear Transformation

Page 7

A transformation *H* is **linear** if, for any inputs $I_1(x,y)$ and $I_2(x,y)$ (in our case input images), and for any constant scalar α we have:

$$H(\alpha I_1(x, y)) = \alpha H(I_1(x, y))$$

and

$$H(I_1(x, y) + I_2(x, y)) = H(I_1(x, y)) + H(I_2(x, y))$$

This means:

- Scaling of the input corresponds to scaling of the output.
- Filtering an additive image is equivalent to filtering each image separately and then adding the results.

Shift-Invariant Transformation

Page 8

• A transformation *H* is **shift-invariant** if for every pair (x_0, y_0) and for every input image I(x,y), such that

$$H(I(x,y)) = R(x,y)$$

$$H(I(x - x_0, y - y_0)) = R(x - x_0, y - y_0)$$

This means that the filter H does not change as we shift it in the image (as we move it from one position to the next).

- If a transformation (or filter) is linear shift-invariant (LSI) then one can apply it in a systematic manner over every pixel in the image.
- Convolution is the process through which we apply linear shift-invariant filters on an image.

$$I \longrightarrow LSI Filter H \longrightarrow R$$

Convolution is defined as:

$$R(x,y) = \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} H(x-i,y-j)I(i,j)$$

and is denoted as:

$$R = H * I$$

Noise, Filtering and Smoothing

Another Look at Convolution

- Filtering often involves replacing the value of a pixel in the input image F with the weighted sum of its neighbors.
- Represent these weights as an image, H
- **H** is usually called the **kernel**
- The operation for computing this weighted sum is called convolution.

$$R = H * I$$

Convolution is:

- commutative, H * I = I * H
- associative, $H_1^*(H_2^*I) = (H_1^*H_2)^*I$
- distributive, $(H_1 + H_2) * I = (H_1 * I) + (H_2 * I)$

Elli Angelopoulou

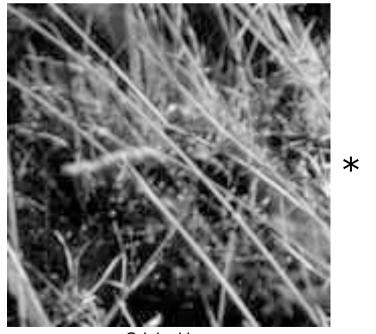

Smoothing via Simple Averaging

One of the simplest filters is the mean filter:
$$H = \begin{bmatrix} \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \\ \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \\ \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \end{bmatrix}$$

In this case, $R(x,y) = \sum_{i=-1}^{1} \sum_{j=-1}^{1} I(x-i, y-j)H(i, j)$

It is used for removing image noise, i.e. for smoothing.

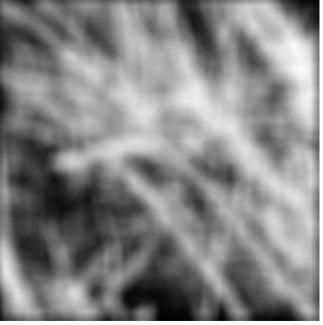

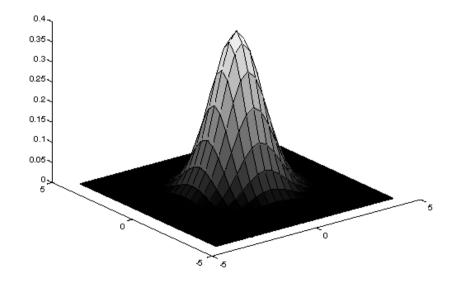

Image after mean filtering (25x25 kernel) Noise, Filtering and Smoothing

Idea: Use a weighted average. Pixels closest to the central pixel are more heavily weighted.

- The Gaussian function has exactly that profile.
- Gaussian also better approximates the behavior of a defocused lens.

Isotropic Gaussian Filter

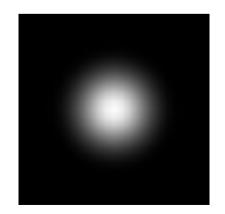

To build a filter H, whose weights resemble the Gaussian distribution, assign the weight values on the matrix H according to the Gaussian function:

$$H(i,j) = e^{-(i^2 + j^2)/2\sigma^2}$$

- Small σ, almost no effect, weights at neighboring points are negligible.
- $H_{Gauss} = \begin{bmatrix} \frac{1}{16} & \frac{1}{8} & \frac{1}{16} \\ \frac{1}{8} & \frac{1}{4} & \frac{1}{8} \\ \frac{1}{16} & \frac{1}{8} & \frac{1}{16} \end{bmatrix}$
- Large σ, blurring, neighbors have almost the same weight as the central pixel.
- Commonly used σ values: Let w be the size of the kernel *H*. Then $\sigma = w/5$.

For example for a 3x3 kernel, σ =3/5=0.6

Noise, Filtering and Smoothing

Compared to mean filtering, Gaussian filtering exhibits no "ringing" effect.

"Ringing" effect

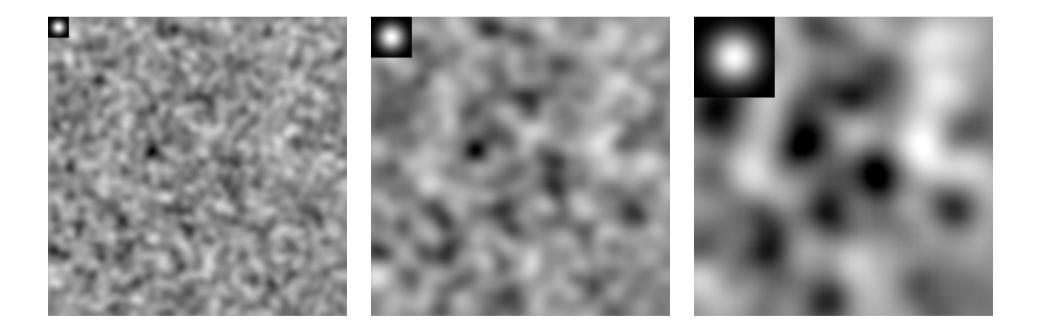

A close look at the frequency response of the two filters show that: compared to Gaussian filtering, mean filtering exhibits oscillations Elli Angelopoulou Noise, Filtering and Smoothing

The Effect of $\boldsymbol{\sigma}$

Page 16

 Different σ values affect the amount of blurring, but also emphasize different characteristics of the image.

- The median filter considers each pixel in the image in turn and looks at its nearby neighbors to decide whether or not it is representative of its surroundings.
- It replaces a pixel value with the median of all pixel values in the neighborhood.
- It is a relatively slow filter, because it involves sorting.
- Can **not** be implemented via convolution.

Smoothing Examples

Mean Filter

Original image

Image after 3x3 Mean filtering

Mean filtering is sensitive to outliers.

It often causes a ringing effect.

It typically blurs edges.

Image after 7x7 Mean filtering

Page 19

Gaussian Filtering and Salt & Pepper Noise

Original image

Image with salt-pepper noise (1% prob. that a bit is flipped)

Image after 5x5 Gaussian filtering, σ =1.0

Image after 9x9Gaussian filtering, $\sigma=2.0$

- Gaussian filtering works very well for images affected by Gaussian noise.
- It is not very effective in removing Salt and Pepper noise.

Median Filtering and Salt & Pepper Noise

Original image

Image with salt-pepper noise (5% prob. that a bit is flipped)

Image after 3x3 Median filtering

Image after 7x7 Median filtering

Image after applying 3 times 3x3 Median filtering

- Median filtering preserves high spatial frequency details.
- It works well when less than half of the pixels in the smoothing window have been affected by noise.
- It is not very effective in removing Gaussian noise.
